AMS4154
2A, 32V Step-Down Converter

General Description
The AMS4154 is a 2A, 330KHz, high voltage step-down converter in a single thermally enhanced exposed paddle SO-8 package. Its wide 6V to 32V input voltage range is ideal for a wide range of applications. These applications include automotive battery requirements where the part achieves 2A of continuous output current for fast charge capability.

The AMS4154 is a current mode control part which provides low ESR ceramic output capacitor stability and fast transient response. Fault protection includes a “hiccup” current limit and thermal protection with hysteresis to protect the device from excessive die temperatures.

With an external \( V_{REF} \) and using only minimum number of readily available external components to compensate, AMS4154 is very flexible for a wide range of applications that requires a 2A step-down DC/DC solution.

Features
- Wide 6V to 32V Input Operating Range
- 34V Absolute Maximum Input
- Up to 2A Output Current
- Low ESR Ceramic Output Capacitor Stable
- Up to 90% Efficiency
- Less than 2µA Shutdown Mode
- 330 KHz Switching Frequency
- Hiccup Mode Over Current Protection
- Output Adjustable From 1.23V to 32V
- Reference Voltage Output
- Thermal Shutdown
- Operating Temperature -40° C to 125° C
- Available in SOIC 8-Pin EDP

Applications
- Automotive Power Adapters
- Automotive Infotainment
- Audio Power Amplifiers
- Portable (Notebook) Computers
- Point of Regulation for High Performance Electronics
- Consumer Electronics
- DVD, Blue-ray DVD writers
- LCD TVs and LCD monitors
- Distributed Power Systems
- Battery Chargers
- Pre-Regulator for Linear Regulation

Typical Application

Figure 1: Functional Block Diagram of AMS 4154
**Device Summary**

The AMS4154 is a high frequency 2A fixed frequency step-down converter. The peak current mode step-down converter is externally compensated and is stable with low ESR ceramic output capacitors. The output voltage is sensed through an external resistive divider that feeds the negative input to an internal transconductance error amplifier. The output of the error amplifier is connected to the input to a peak current mode comparator. The inductor current is sensed as it passes through the high side power switch and fed to the current mode comparator. The error amplifier regulates the output voltage by controlling the peak inductor current passing through the power switch so that, in steady state, the average inductor current equals the load current. The step-down converter has an input voltage range of 6V to 32V with an output voltage as low as 1.23V.

**Enable**

The enable threshold for the step-down converter is 2.5V with 100mV of hysteresis.

**Fault Protection**

Short circuit protection limits the peak current and initiates a “hiccup” mode of operation to limit the input power during short circuit operation. Over-temperature shutdown disables the converter when the junction temperature reached 150°C.

**Application**

**Inductor**

The step-down converter inductor is typically selected to limit the ripple current from 20% to 40% of the full load output current. Meeting this rule of thumb also guarantees the internal slope compensation is greater than one half of the inductor current down-slope thus avoiding any peak current mode related instability when the duty cycle is greater than 50%.

\[
L = \left(\frac{V_{\text{IN}} - V_{\text{OUT}}}{V_{\text{OUT}} \cdot 10 \cdot 0.4 \cdot F_s}\right) \frac{V_{\text{OUT}}}{V_{\text{IN}} \cdot 10 \cdot 0.4 \cdot F_s}
\]

\[
L = \left(\frac{12V - 3.3V}{12V \cdot 2A \cdot 0.4 \cdot 330KHz}\right) = 10\mu H
\]

For most applications the duty cycle of the AMS4154 step down converter is less than 50% duty and does not require slope compensation for stability. This provides some flexibility in the selected inductor value. Given the above selected value, others values slightly greater or less may be examined to determine the effect on efficiency without a detrimental effect on stability. With the inductor value selected, the ripple current can be calculated:

\[
I_{\text{pp}} = \frac{V_{\text{OUT}}(1-D)}{L \cdot F_s}
\]

\[
I_{\text{pp}} = \frac{3.3V(1-(3.3V/12V))}{10\mu H \cdot 330KHz} = 0.725A
\]

Once the appropriate value is determined, the component is selected based on the DC current and the peak (saturation) current. Select an inductor that has a DC current rating greater than the full load current of the application. The DC current rating is also reflected in the DC resistance (DCR) specification of the inductor. The inductor DCR should limit the inductor loss to less than 2% of the step-down converter output power. The peak current at full load is equal to the full load DC current plus one half of the ripple current.

\[
I_{\text{PEAK_MAX}} = I_{\text{OUT}} + \frac{V_{\text{OUT}}(1-D)}{2 \cdot L \cdot F_s}
\]

\[
D = \frac{V_{\text{OUT}}}{V_{\text{IN}}}
\]

\[
D = \frac{3.3V}{12V} = 0.275
\]

\[
I_{\text{PEAK_MAX}} = 2A + \frac{(3.3V)(1-0.275)}{2 \cdot 10\mu H \cdot 330KHz} = 2.363A
\]

\[
I_{\text{pp}} = \frac{(3.3V)(1-0.275)}{12\mu H \cdot 330KHz} = 0.725A
\]
There is a wide range of 3A and above shielded and non-shielded inductors available. Table 1 lists a few inductors that have a current rating of 3A and higher.

**Output Capacitor**

A low ESR X5R or X7R type ceramic capacitor is typically sufficient for most applications. The following equation determines the required low ESR ceramic output capacitance for a given inductor current ripple (I\(_\text{PP}\)) and a (dV\(_\text{OUT}\)) limit of 200mV.

\[
\text{C}_{\text{OUT}} = \frac{I_{\text{PP}} \cdot F_s \cdot 8 \cdot \text{dV}_{\text{OUT}}}{800 \cdot \text{KHz} \cdot 8 \cdot 200 \text{mV}} = 1.37 \mu\text{F}
\]

For applications with large load transients, additional capacitance may be required to keep the output voltage within the specified limits. In this case, the required capacitance can be examined for the load application and load removal. From a full load to no load transient, the required capacitance to limit the output voltage overshoot to less than 200mV for a 3.3V output is:

\[
\text{C}_{\text{bulk}} = \frac{L \cdot I_{\text{OUT}}^2}{V_{\text{OUT}+\text{OS}}^2 - V_{\text{OUT}}^2} = \frac{10 \mu\text{H} \cdot (2\text{A})^2}{(3.5\text{V})^2 - (3.3\text{V})^2} = 29.4 \mu\text{F}
\]

For the application of a load pulse, the capacitance required from hold up depends on the time it takes for the power supply loop to build up the inductor current to match the load current. For the AMS4154 this can be estimated to be less than 10 usec or about three clock cycles. For a no load to 1A load pulse the required capacitance to limit the voltage droop to less than 200mV is estimated from:

\[
\text{C}_{\text{OUT}} = \frac{I_{\text{OUT}} \cdot \text{t}}{200 \text{mV}} = 1\text{A} \cdot 10\text{usec} = 50 \mu\text{F}
\]

**Boot Strap Capacitor**

An external boot strap capacitor (C\(_\text{BST}\)) is required for the high side switch drive. The capacitor is charged during the off time while the switch node is at ground. During the on-time portion of the switching cycle the switch node is tied to the input voltage by way of the internal power switch. The boot strap capacitor is always referenced to the switch node so the charge stored in the capacitor during the off time is then used to drive the internal power switch during the on-time. Typical bootstrap capacitor values are in the 470nF to 1\mu F range. A type X5R ceramic with a 10V rating. Insufficient values will not be able to provide sufficient base drive current to the power switch during the on time. Values less than 470nF are not recommended. This will result in excessive losses and reduced efficiency.

**Output Rectifier Diode**

The output freewheeling rectifier (D\(_1\)) provides a path for the inductor current to flow when the high side integrated power switch is off. A Schottky diode is usually preferred because of its very low forward voltage and recovery time.

The diode reverse voltage rating must be greater than the maximum input voltage rating. The diode conducts the full load current during the off time and therefore should have an average current rating greater than the load current times the one minus the duty cycle.

\[
I_{\text{D1}} \geq I_{\text{OUT}} \cdot (1-D) = \frac{V_{\text{OUT}}}{V_{\text{IN}}} = 2\text{A} \cdot \frac{3.3\text{V}}{12\text{V}} = 1.45\text{A}
\]

**Input Capacitor**

The low ESR ceramic capacitor is required at the input to filter out high frequency noise as well as switching frequency ripple. Placement of the capacitor is critical for good high frequency noise rejection. See the PCB layout guidelines section for details. Switching frequency ripple is also filtered by the ceramic bypass input capacitor. Given a desired input voltage ripple ($V_{\text{RIPPLE}}$) limit (typical $V_{\text{RIPPLE}} \approx 100\text{mV}$), the required input capacitor can be estimated with:

$$D = \frac{V_{\text{OUT}}}{V_{\text{IN}}}$$

$$C_{\text{IN}} = \frac{D \cdot I_{\text{OUT}} \cdot (1-D)}{F_s \cdot V_{\text{RIPPLE}}}$$

$$C_{\text{IN}} = \frac{3.3V}{12V} \cdot 2A \cdot \left( \frac{3.3V}{12V} \right) = \frac{1}{330\text{KHz} \cdot 100\text{mV}} = 12\mu\text{F}$$

For high voltage input converters the duty cycle is always less than 50% so the maximum ripple is at the minimum input voltage. The ripple will increase as the duty cycle approaches 50% where it is a maximum.

**Feedback Resistor Selection**

The converter uses a 1.23V reference voltage at the positive terminal of the error amplifier. To set the output voltage, a programming resistor from the feedback node to ground must be selected (R1 and R3 of figure 2). A 10KΩ resistor is a good selection for a programming resistor R3. A higher value could result in an excessively sensitive feedback node while a lower value will draw more current and degrade the light load efficiency. The equation for selecting the voltage specific resistor (R1) is:

$$R1 = \frac{V_{\text{OUT}}}{V_{\text{REF}}} - 1 \cdot R3 = \left( \frac{3.3V}{1.23V} - 1 \right) \cdot 10K\Omega = 16.9K\Omega$$

**Compensation**

The loop gain of the converter consists of three parts, the power stage or plant ($G_{\text{PWR}}$), the feedback network which sets the output voltage ($G_{FB}$) and the error amplifier along with the compensation network ($G_{\text{COMP}}$).

When using low ESR ceramic output capacitors the gain of the power stage in the crossover frequency region is the peak current loop gain times the output capacitance.

$$G_{\text{PWR}} = \frac{G_{CS}}{2 \pi F_s C_{\text{OUT}}}$$

In the above equation, ($F_s$) is the switching frequency, $G_{CS}$ is the COMP to current sense transconductance and $C_{\text{OUT}}$ is the output capacitance.

The error amplifier gain in the crossover frequency range is the error amplifier transconductance multiplied by the R2 of output compensation network.

$$G_{\text{COMP}} = G_{EA} \cdot R2$$

The feedback resistor network is simply a resistive divider.

$$G_{FB} = \frac{R3}{R3 + R1} = \frac{10K}{10K + 16.9K} = 0.37$$

For unity gain crossover (0dB) gain simply set the total loop gain to unity and solve for the compensation resistor value. In this example the crossover frequency is set at one tenth of the switching frequency.

$$G_{\text{COMP}} \cdot G_{\text{PWR}} \cdot G_{FB} = \frac{G_{EA} \cdot G_{FB} \cdot R2 \cdot G_{CS}}{2 \pi \cdot 0.1 \cdot F_s \cdot C_{\text{OUT}}} = 1$$

$$R2=\frac{2 \pi \cdot 0.1 \cdot F_s \cdot C_{\text{OUT}} \cdot 22\mu\text{F}}{G_{EA} \cdot G_{CS} \cdot G_{FB} \cdot 245\mu\text{A/V} \cdot 4\text{A/V} \cdot 0.37} \approx 13\Omega$$

To provide sufficient phase margin at the crossover frequency set the compensation zero a decade below the crossover frequency.

$$C6 = \frac{4}{2 \pi \cdot R2 \cdot 0.1 \cdot F_s} = \frac{4}{2 \pi \cdot 13\Omega \cdot 0.1 \cdot 330\text{KHz}} = 1.5nF$$
In cases where the additional high frequency pole is desired, C7 can be added with the pole placed at approximately (10X) the compensation zero frequency.

**Output Power and Thermal Limits**

The AMS4154 junction temperature and output current capability depends on the internal dissipation and the junction to case thermal resistance of the SO8 exposed paddle package. This gives the junction temperature rise above the ambient temperature.

The temperature of the PCB will be elevated above the ambient temperature due to the total losses of the step down converter and losses of other circuits and or converters mounted to the PCB.

\[ T_{J_{\text{max}}} = P_d \cdot \theta_{JC} + T_{PCB} + T_{AMB} \]

The losses associated with the AMS4154 overall efficiency are:
1. Inductor DCR Losses
2. Freewheeling Diode (catch diode)
3. AMS4154 Internal losses
   a. Power Switch VCESAT “on” losses
   b. Quiescent Current losses

The internal losses contribute to the junction temperature rise above the case and PCB temperature.

The junction temperature depends on many factors and should always be verified in the final application at the maximum ambient temperature. This will assure that the device does not enter over-temperature shutdown when fully loaded at the maximum ambient temperature.

**PCB Layout**

The following guidelines should be followed to ensure proper layout.

1. V_{IN} Capacitor. A low ESR ceramic bypass capacitor must be placed as close to the IC as possible.
2. Feedback Resistors. The feedback resistors should be placed as close as possible to the IC. Minimize the length of the trace from the feedback pin to the resistors. This is a high impedance node susceptible to interference from external RF noise sources.
3. Inductor. Minimize the length of the SW node trace. This minimizes the radiated EMI associated with the SW node.
4. Ground. The most quiet ground or return potential available is the output capacitor return. The inductor current flows through the output capacitor during both the on time and off time, hence it never sees a high di/dt. The only di/dt seen by the output capacitor is the inductor ripple current which is much less than the di/dt of an edge to a square wave current pulse. This is the best place to make a solid connection to the IC ground and input capacitor. This node is used as the star ground shown in Figure 2. This method of grounding helps to reduce high di/dt traces, and the detrimental effect associated with them, in a step-down converter. The inductance of these traces should always be minimized by using wide traces, ground planes, and proper component placement.
